SUMMARY

There is an increased public awareness of the importance of wetlands and a heightened interest in restoration and creation of wetlands using dredged material. Dredged material is being tested for potential use in wetland creation and restoration projects. In order to evaluate the acceptability of wetland creation and restoration with dredged material, establishment of some form of reference wetland baseline from which to make informed evaluations is often necessary. Test data must be interpreted in relationship to realistic circumstances. The reference baseline is usually chosen from the particular location where wetlands will be created or restored.

The objective of this study was to determine the concentrations of contaminants in sediments, plants and animals in existing wetlands near proposed wetland creation sites and to establish a reference wetland baseline for the San Francisco Bay area. The data collected would become an initial wetland baseline that can be used to interpret and put perspective on results of wetland testing of dredged material from the San Francisco Bay area.

Thirteen naturally occurring wetlands were sampled in marine, estuarine and freshwater locations along San Francisco and Suisun Bays and in the Sacramento River Basin. Wetland sediment, plant and animal samples were collected and transported to the U.S. Army Engineer Waterways Experiment Station (WES) for processing and analysis. Samples were analyzed for metals, butyltins, petroleum aromatic hydrocarbons, pesticides and polychlorinated biphenyls.

The naturally-occurring wetlands in the San Francisco Bay area and the adjacent estuarine and freshwater areas contained relatively low levels of most metal, PCBs, PAHs, butyltin, and pesticide contaminants in soil/sediment, plants, and animals. Metals such as lead, chromium and arsenic appeared to have elevated concentrations in some plants and animals. There was a very depauperate faunal component in all the naturally-occurring wetlands surveyed, that may be the result of a more subtle impact. This survey was conducted toward the end of a five year drought in the region. This climatic condition no doubt influenced the existing fauna available for sampling.

PREFACE

This report presents the results of a field survey of existing wetlands in the San Francisco Bay area performed for Messrs. Brian Walls, Duke Roberts, Mark Dettle and Tom Kendall, project managers at the San Francisco District of the US Army Corps of Engineers. The study was conducted by the US Army Engineer Waterways Experiment Station (WES) during the period July 1990 through September 1991.

Work was performed by Dr. Charles R. Lee, Soil Scientist; Dr. Henry E. Tatem, Zoologist; Dr. John W. Simmers, Research Biologist; Mr. Richard A. Price, Research Agronomist; Mr. Dennis L. Brandon, Statistician; Contaminant Mobility and Regulatory Criteria Group (CMRCG), Environmental Processes and Effects Division (EPED), Environmental Laboratory (EL); and Mr. Scott P. Miner, Ecologist, San Francisco District, U.S. Army Corps of Engineers (SPN).

Animal bioassessment acknowledges Mr. Lawrence Bird (ASCI Corporation), and Ms. Heather Holifield, Mr. Michael Pendarvis, and Mr. Johnny McGuffie (University Contract Students) for conducting the laboratory portion of this study. Plant bioassessment acknowledges Ms. Erika Seals and Ms. Elizabeth Tominey (University Contract Students) for laboratory processing and analysis of sediment and plant tissue. Heavy metals analyses of samples from the plant bioassay were provided by the Analytical Laboratory Group, Environmental Engineering Division, USAE-WES, Vicksburg, Mississippi. All other chemical analyses of sediment, water, and tissues were performed by Dr. Eric Crecelius, Battelle/Marine Sciences Laboratory, Sequim, WA.

At the time of the study, work was conducted under the supervision of Dr. Bobby L. Folsom, Jr., Chief, CMRCG; Mr. Donald L. Robey, Chief, EPED; Dr. John Harrison, Chief, EL, and Mr. Roderick A. Chisholm II, Chief, Environmental Branch, SPN.

At the time of the study, COL Larry Fulton, EN, was Commander and Director during the preparation of this report. Technical Director was Dr. Robert W. Whalin.

This report should be cited as follows:

I. INTRODUCTION

Background

Each year the Corps of Engineers dredges sediment from harbors and channels throughout the San Francisco Bay Area to maintain navigation and commerce. Productive use of dredged material to restore and create wetlands has gained more interest in recent years. Suitable dredged material has been used productively in over 120 locations across the U. S. (US Army EM-1110-2-5026). The importance of wetlands to the productivity of estuaries has been realized even more recently in the San Francisco Bay Area. A heightened public interest has emerged to restore wetland acreage that has dwindled away over the past 50 years. Consequently, there has been increased public desire to create and restore wetlands in the San Francisco Bay area in recent years. Dredged material was thought to be of potential value in wetland creation or restoration.

Purpose and Scope

The purpose of this report is to describe the results of a field survey of existing wetland sites in the San Francisco Bay Area and to establish a wetland baseline data set.

Objectives

The objectives of the survey were:

- 1) to identify relatively undisturbed wetlands typical of the San Francisco Bay area;
- 2) to collect samples of the dominant plants, animals (where present) and wetland soil from selected marine and estuarine wetlands in the vicinity of San Francisco Bay;
- 3) to analyze each plant tissue, animal tissue, and soil sample for the presence of contaminants, including toxic heavy metals, polychlorinated biphenyls (PCBs), polycyclic aromatic hydrocarbons (PAHs), and butyltin compounds such as Tributyltin (TBT);

4) to document the location and appearance of each of the sampling sites for future reference by map location and through aerial photographs.

II. FIELD SURVEY

Approach

The interpretation of the results of biological and chemical testing of a sediment to evaluate its potential use in wetland creation requires a yardstick (i.e. reference database) for comparison. For this reason, naturally-occurring wetlands in the San Francisco Bay area were identified and the soil/sediment and the indigenous plant and animal communities were sampled. In coordination with personnel of the USACE San Francisco District, sites were selected that are considered to be typical undisturbed wetlands by the District and the Federal and State resource agencies. Unfortunately, since settlement, the San Francisco Bay Area has been the source of anthropomorphic disturbance that has resulted in both modification of the pre-settlement landscape and the introduction of numerous plant and animal species. As a result, it is not always possible to locate the desired species or a sufficient biomass of the desired species for analysis. During the summer of 1990, when the field survey was conducted, animal species, live populations of bivalve mollusks in particular, were not present in either the marine or estuarine wetlands. The paucity of animals has certainly limited the comparative value of the following survey, however, the plant and sediment/soil collections do provide a suitable data base for the establishment of a baseline for wetlands in the San Francisco Bay Area comparison with the species employed in the mesocosm test procedures.

Methods and Materials

Site Selection. The initial selection of the wetlands to be considered was provided by the USACE San Francisco District personnel and consisted of wetlands selected within known wetland refuges and locations generally thought to have been little affected by anthropomorphic activities during recent years, or as in the case of Site 8, the disturbance was well documented and the site was of

interest to the District.

The potential sites were surveyed from the air and if there were no obvious reasons to reject the site, such as proximity to industrial activity, a location within the site was selected for the field sampling (Figure II-1). On several occasions if the helicopter employed by the field collection personnel was not able to land, if the field crew was not able to reach a suitable plant community due to dense vegetation once landed, or if the appropriate plant species were not present, the collection site was relocated as required.

Plant and Animal Identification. Plants and animals collected were identified using appropriate resource materials and reports such as Fernald (1950), Josselyn (1983), and Gosner (1979). Where appropriate, local botanists were consulted to confirm the plant identifications in the field.

Field Collection Technique. Locations of field collections, water salinity, and plant and animal species collected are given in Table II-1. In the marine wetland areas Spartina foliosa and Salicornia subterminalis were the predominate species. Spartina was collected from the low marsh (nearest the water) and Salicornia was collected from the high marsh (the zone inland from the Spartina). In general, two samples of Spartina labeled A and B were collected from the intertidal, low marsh and two samples of Salicornia labeled C and D were collected from the more upland, high marsh. In the estuarine and fresh water areas of the survey, the dominant low and high marsh plants were collected as before, labels A and B designated low marsh and C and D designated high marsh. Due to the variability of the less marine habitats, plant species varied between Typha, Scirpus, and Salicornia, depending on the wetland area. Each sample collected consisted of the amount of plant material that could be encompassed by a 28.7-cm square made from a folding carpenter's ruler, or 823.7 cm². The plants were clipped 5 cm above the ground. Plant material from each sample was placed in a Ziploc bag or a trash can liner, depending on the amount of vegetation, and placed on ice for shipment to the WES.

After the plants were collected a soil sample of the surface material was collected from each of the sampling locations, A-D. Soil samples were placed in Ziploc bags and placed on ice for shipment to WES. A refractometer was used to measure the salinity of the water.

Any animals suitable as sentinel species were collected at each field collection site. Animal collections represent a composite sample rather than two discrete points within the field site. When a single species was found in sufficient numbers to provide appropriate biomass for chemical analysis, the animals were collected, placed in Ziploc bags and placed on ice for shipment to WES.

At each site the location was plotted on a map (Figures II-2, II-3, and II-4) and an aerial photograph was made of the site, looking north at 30- to 45-m altitude (Figure II-5 - II-16).

Laboratory Procedures. Plant, animal, and soil samples were shipped and stored at 4°C until processed. The plant leaf samples were rinsed three times in reverse osmosis (RO) purified water blotted with paper towels, and weighed. Animal sentinel species (mollusks) were rinsed in RO water and the soft tissues removed from the shells. Only the soft tissues were submitted for chemical analysis. Soil samples were composited to form one sample from each field site. Plant tissue, animal tissue, and soils were placed in acid-washed, hexane-rinsed glassware and shipped at 4°C to Battelle Pacific Northwest Laboratory for chemical analysis. Freeze dried and ground sediment samples were analyzed by energy dispersive X-ray fluorescence for As, Cr, Cu, Ni, Pb and Zn (Nielson and Sanders 1983). The other metals were analyzed by atomic absorption spectrometry (AA) after the sediment was totally dissolved in a mixture of nitric, perchloric and hydrofluoric acids at an elevated temperature (130 degrees C) in a sealed Teflon container. Mercury was quantified by cold vapor atomic absorption spectrometry and the other metals (Ag, Cd and Sb) were quantified by Zeeman graphite furnace AA with matrix modifiers. Sediment and tissue samples were extracted with a mixture of methylene chloride, tropolone and sodium sulfate for

the Tributyltin (TBT) analyses. The extract was derivatized and analyzed by gas chromatography with a flame photometric detector (GC-FPD) similar to the method of Ungery et al. (1986). Sediments were analyzed for base-neutral acids using US EPA Method 625, which indicates solvent extraction, column cleanup and the quantification by GC/MS. The PCBs and DDT were analyzed by US EPA Method 8080 which quantified by GC-ECD. Volatiles were analyzed by US EPA Method 624 using GC/MS. All samples for tributyltin analyses were placed in hexane rinsed and oven-dried amber glass containers and frozen prior to shipping.

Results and Discussion

Chemical Analysis. Results of the analyses for metal, butyltin, PAH, PCB, and pesticide contaminants are shown in Tables II-2 through II-6. Metal concentrations (Table II-3) represent naturally-occurring background levels for the enormous San Francisco Bay area. These levels of metals result from the presence of heavy metals in the earth's crust, water borne metals, metals in tide water and any atmospheric fallout. These data represent areas thought to be relatively undisturbed, and uncontaminated by agricultural or industrial activities (Site 8 however, was the only disturbed site that had been created from dredged material). While the sediment arsenic concentrations are relatively low and range up to 23.7 mg/kg for site 1 and plant tissue contents are at or below detection limits, those few animals collected had tissue arsenic concentrations approaching or at a FDA-type tissue arsenic content of 10 ug/g (dry weight basis) for mollusks and crustacea used by Australia (Lee et al. 1991). While the few animals sampled in this field survey did not show elevated levels of chromium, zinc or lead, snails collected from the Tiburon area and used in wetland bioassays of dredged material from Oakland Harbor and J. F. Baldwin Ship Channel showed levels of chromium up to 74.9 ug/g, zinc up to 797 ug/g and lead up to 31.6 ug/g (Lee et al. 1994). These bioassays were conducted at the same time of the Field Survey and indicate that chromium, zinc and lead concentrations in certain native wetland animals may be elevated in the San Francisco Bay area. Of particular concern is the lead levels that appear to approach and exceed the 25 ug/g lead concentration established in Australia for human consumption of mollusc. Both Spartina and Salicornia plant species collected during the Field Survey showed tissue lead concentrations up to 4.9 and 5.4 ug/g, respectively. These values approach and exceed the 5.0 ug/g concentration established by the Dutch for mixed animal feed (van Driel et al. 1985). These data suggest that lead contents of some wetland plants and certain wetland animals in existing wetlands may be of concern to the foodwebs associated with these sites in the San Francisco Bay area. The presence of copper at what may appear to be an elevated level in the animals collected at the field sites is likely related to the copper-containing respiratory pigment

characteristic of the Mollusca as a group. The butyltin levels are generally near or below detection limits with the exception of tributyltin in bivalve mollusks (Table II-2). Butyltin values in boldface print are above detection limits. Modiolus collected at Site 1 contained 34.9-38.3 ug/kg tributyltin and Corbicula collected at Site 13 contained 40.7 ug/kg. These levels are the highest determined in any survey animals and probably reflect trace amounts accumulated from the water filtered by these mollusks. Since butyltins do not exist in nature, the levels reported are assumed to be the result of contamination from marine antifouling coatings. PCBs were not found above the detection limits with the exception of some trace amounts of Aroclor 1254 in the wetland soils collected at Sites 1-4 (Table II-4). As noted for butyltin compounds, PCBs are not found naturally in the environment and their presence above detection limits indicates some anthropomorphic contamination. The presence of some PAHs at levels greater than detection in the wetland soils at some sites may also be indicative of anthropomorphic influences (Table II-5). Those PAHs indicated in boldface print are above the detection limits but at the same time they are still relatively low and generally do not exceed 50-100 ug/kg. Pesticides were notably below detection limits with only a few exceptions (boldfaced in Table II-6).

The naturally-occurring wetlands in the San Francisco region that were selected for this survey appeared to be relatively uncontaminated by post-settlement agriculture and industrialization. Even Site 8 constructed on dredged material contained only low levels of the contaminants evaluated. Arsenic tissue contents observed in the few animals collected appeared to be close or at the action level established in Australia for mollusks and crustacea. Further study of arsenic in wetland foodwebs in the San Francisco Bay area appears to be warranted. Likewise, some wetland plants and animals were observed to contain elevated levels of chromium, zinc and/or lead. Lead particularly was observed to approach and exceed tissue lead contents established for plant feed mixes by the Dutch and lead concentrations in mollusks established by the Australian. Further evaluation of chromium, zinc and lead in existing wetlands of San Francisco Bay appears to be warranted.

Although the levels of anthropomorphic contaminants appear to be low, all the selected sites were characterized by a lack of animals, particularly those that could have been used as sentinel species. All the marine sites were characterized by the dead remains of what must have only recently been extensive beds of ribbed mussels. Although the plant communities have survived, there is a need to at least develop a plausible explanation for the lack of living mussels. The introduction and proliferation of a tiny exotic clam from Asia, Potamocorbula amurensis may be a contributing factor. This species out-competes and is a more efficient feeder than existing species. In the brackish and freshwater sites, the clam Corbicula was represented also by many shells and only a few live animals. The invasion of Potamocorbula amurensis also includes brackish waters such as in Suisun Bay. Snails were equally scarce on all sites but Site 8. This lack of animals is quite peculiar since the snails, and mussels are invasive species from the U. S. East Coast, and the clams are an equally opportunistic species from Asia. While it is likely that the introduction of the exotic species (Nassarius, Modiolus, and Corbicula) accompanied some disturbance of the California wetlands, these are very hardy species and would have been expected to survive subsequent disturbances. However, Potamocorbula amurensis could even be out-competing these species. It is realized that the entire San Francisco Bay area has suffered from an extensive drought over the past five years and could have contributed to the observation of few live animal species in the wetlands sampled. Likewise, the faunal component of San Francisco Bay wetlands is not well documented and perhaps the fauna may not be particularly diverse or abundant in the West Coast wetlands.

Table II-1. Wetland Field Survey Site List of Samples Collected.

Site	Location	Samples
1	Hamilton Air Force Base/Antenna Field Natural saltmarsh, 26 ppt. Selected as reference marsh for laboratory tests	<i>Spartina foliosa</i> (2) ⁺ <i>Salicornia</i> sp. (2) Mussels (1) Soil (4)

III. CONCLUSIONS AND RECOMMENDATIONS

The naturally-occurring wetlands in the San Francisco Bay area and the adjacent estuarine and fresh water areas appear to contain relatively low levels of most metal, PCB, PAH, butyltin, and pesticide contaminants in soil/sediment, plants, and animals. Metals such as lead, chromium and arsenic appeared to have elevated concentrations in some plants and animals. There is, however, a very depauperate faunal component in all the naturally occurring wetlands surveyed, that may be the result of a more subtle impact. The introduction and proliferation of a tiny exotic clam from Asia, Potamocorbula amurensis may be a contributing factor. This species out-competes and is a more efficient feeder than existing species. In the brackish and freshwater sites, the clam Corbicula was represented also by many shells and only a few live animals. The invasion of Potamocorbula amurensis also includes brackish waters such as in Suisun Bay. Snails were equally scarce on all sites but Site 8. This lack of animals is quite peculiar since the snails, and mussels are invasive species from the U. S. East Coast, and the clams are an equally opportunistic species from Asia. While it is likely that the introduction of the exotic species (Nassarius, Modiolus, and Corbicula) accompanied some disturbance of the California wetlands, these are very hardy species and would have been expected to survive subsequent disturbances. However, Potamocorbula amurensis could even be out-competing these species. This survey was conducted toward the end of a five year drought experienced in the region. This climatic condition no doubt influenced the existing fauna available for sampling. Further documentation of the fauna of the San Francisco Bay area wetlands appears to be warranted. In addition, further evaluation of the status of arsenic, lead and chromium in wetland foodwebs in the San Francisco Bay area.

The data presented in this report establishes an initial baseline for wetlands in the San Francisco Bay Area and can be used to interpret wetland test results for wetland creation or restoration projects. As more information becomes available, this baseline should be updated to include all ongoing and future data collection activities.

REPORT DOCUMENTATION PAGE

**Form Approved
OMB No. 0704-0188**

Public reporting burden for this collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing this collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden to Department of Defense, Washington Headquarters Services, Directorate for Information Operations and Reports (0704-0188), 1215 Jefferson Davis Highway, Suite 1204, Arlington, VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to any penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number. PLEASE DO NOT RETURN YOUR FORM TO THE ABOVE ADDRESS.

13. SUPPLEMENTARY NOTES					
14. ABSTRACT The importance of wetlands to the productivity of estuaries has been realized in the San Francisco Bay Area. A heightened public interest has emerged to restore wetland acreage that has dwindled away over the past 50 years. Dredged material was thought to be of potential value in wetland creation or restoration. This report presents the results of a field survey of existing wetland sites in the San Francisco Bay Area. Dominant plants, of existing wetland sites in the San Francisco Bay Area. Dominant plants, animals (where present) and wetland soil from selected marine and estuarine wetlands were sampled and analyzed for contaminants. These data will be used to establish a wetland reference database. Sediment biological and chemical test results concentrations will be compared to the reference database to evaluate its potential use in wetland creation.
